

Space-saving water storage

Water reservoir under the staging

Water is stored in a variety of ways. Less well-known than the excavated water reservoirs and water silos, but just as effective, are the water reservoirs under the staging in the greenhouse. The space is available and land is expensive so why not make optimum use of the storage capacity in the greenhouse? The principle is simple; the reservoirs have the same length and width as the staging, they are excavated, a waterproof lining is installed and the top is fitted with a tensioned cover so that no materials can fall into the reservoir.

Underground water storage

Another form of space-saving water storage is underground water storage in the shape of the Klimrekbuffer®. This method is ideal for storing both warm water and irrigation water.
